Qns 66 to 70 : Read the passage given and answer the questions that follow.

The colours you see in flowers come from the DNA of a plant. Genes in a plant's DNA direct cells to produce pigments of various colours. When the flower is red, it means that the cells in the petals have produced a pigment that absorbs all colours but red. When you look at that flower, it reflects red light. So, the flower appears to be red. Flowers are the reproductive parts of plants. They attract insects to pick up pollen and transfer it to other plants and flowers. This helps the plant to reproduce. Some flowers change colour or fade over time. This is an indication to the pollinators that pollination is no longer needed. Many of the actual chemicals in the petals of a flower are called anthocyanins. These are water soluble compounds that belong to a bigger class of chemicals called flavonoids. Anthocyanins are responsible for creating blue, red, pink, pink and purple colours in flowers. Other pigments that produce floral colours include carotene (for red and yellow), chlorophyll (for green in petals and leaves) and xanthophyll (a pigment that produces yellow colours).
